Perfect security

Is there a cipher that is unbreakable?

Shannon 1949

Communication Theory of Secrecy Systems* By C. E. SHANNON

1. Introduction and Summary

Title problems of cryptography and secrecy systems furnish an intersting application of communication theory. It this page at theory of the secrecy systems is developed. The approach is on a theoretical level and is intended to complement the treatment found in standard works on cryptography. There, a detailed study is made of the many standard types of codes and cipbers, and of the ways of breaking them. We will be more concerned with the general mathematical structure and properties of secrecy systems.

The treatment is limited in certain ways. First, there are three general types of servery system; (louenglanes types, including such methods as invisible ind., concending a message in an innocent text, or in a lake over-ing cryptogram, or forter methods in which the existence of the message is concaided from the enemy; (2) privacy systems, for example speech inversions which the contraction of the enemy o

technologies for.

Secondly, thought there is limited to the case of discrete information. Secondly, thought the property of t

The paper is divided into three parts. The main results will now be briefly summarized. The first part deals with the basic mathematical structure secrecy systems. As in communication theory a language is considered to "The material in this paper appeared originally in a confedential report "A Mathematical Theory of Cryptography" dated Sept. 1, 1948, which has now ben declassified.

"The material in this paper appeared originally in a confidential report "A Malhematical Theory of Cryptography" dated Sept. 1, 1948, which has now been declassified. Journal, July 1948, p. 339, Ver. 1948, p. 637.

Sept. for example, H. F. Gaines, "Elementary Cryptanalysis," or M. Givierge, "Cours de Cryptographic."

Vernam cipher, one-time pad, 1917

t	k	$c = t \oplus k$
0	0	0
0	1	1
1	0	1
1	1	0

Table: XOR $t \oplus k$

Thus you you have a text (t) and key (k) then you can get an encoded text as follows

$$c = t \oplus k$$

original text can be restored as

$$t = c \oplus k$$

Key distribution. Discrete log

$$x = ind_g(a) \mod p$$

min x such that

$$g^{x} \equiv a \mod p$$

Key distribution. Diffie-Hellman

Known data: g, p

Alice choose random a and calculates

$$A \equiv g^a \mod p$$

Bob choose random b and calculates

$$B \equiv g^b \mod p$$

Alice and Bob exchange the A and B and calculate K as

$$K \equiv B^a \mod p$$

or

$$K \equiv A^b \mod p$$

Einstein-Podolsky-Rosen paradox

A. Einstein

B. Podolsky

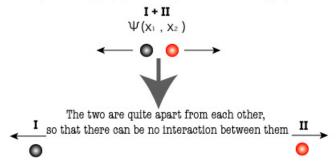

N. Rosen

Heisenberg inequality

$$\Delta p \Delta q \geq rac{\hbar}{2}$$

Einstein-Podolsky-Rosen paradox

EINSTEIN-PODOLSKY-ROSEN PARADOX, (1)

Suppose you measure the momentum of the black particle (I); then you can know the momentum of the red particle (II) as well. Likewise, if you measure the position of the black, then you can know the position of the red as well. In both cases, the measurement can be done without disturbing the red (since there can be no interaction between the black and the red).

Einstein-Podolsky-Rosen paradox

EINSTEIN-PODOLSKY-ROSEN PARADOX, (2)

If you measure the momentum **p**, then the momentum of the red is **-p**. Since the momentum of the red was measured without disturbing it, that quantity must be regarded as **real**.

If you measure the position q_i , then the position of the red is q_2 . Since the position of the red was measured without disturbing it, that quantity must be regarded as **real**.

Ivan Murashko

Bell experiment. Classical case

$$f = \frac{1}{2} (ab + a'b + ab' - a'b'), a, a', b, b' \in \{-1, +1\}.$$

therefore $f \in \{-1, +1\}$ and $|\langle f \rangle| \leq 1$

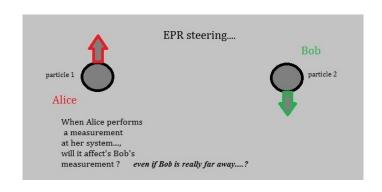

Bell experiment. Quantum case

$$|\langle f \rangle| = \sqrt{2} > 1$$

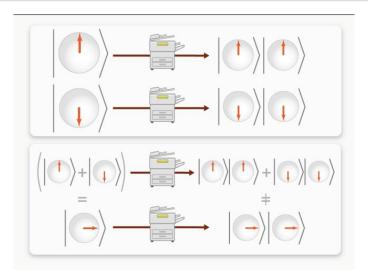

Quantum cryptography. Base principles

- Measurement is random
- Alice and Bob measurements are correlated
- No-cloning theorem

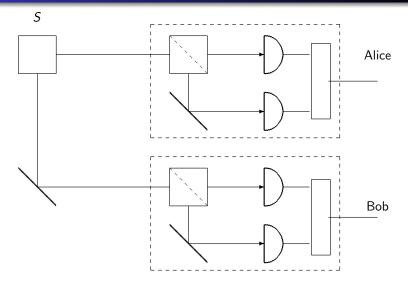

Measurement is random but correlated

No-cloning theorem

Quantum cryptography. Key distribution
